## Introduction

- The International Tundra Experiment (ITEX), with many research sites throughout the world, was established in 1990 to understand how environmental change impacts Arctic and alpine ecosystems, and has resulted in high-impact across-site syntheses.
- Various add-on projects in ITEX sites have resulted in increasing knowledge of many components of local ecosystems, which is a good starting point for within-site syntheses to better understand ecosystem responses to environmental change across ecological scales.
- We have synthesized 80 studies on ecological responses to environmental change at the Finse ITEX site in alpine Norway.

## Where, how and why?

Increased temperatures due to climate change will impact the biodiversity of alpine areas<sup>1</sup>. One of the most diverse plant communities in Scandinavia and the Alps are heaths. We studied changes in the alpine heath at Finse, SW Norway, after 23 years of experimental warming (Fig. 1). We expected warming to increase dwarf shrub and graminoid cover at the expense of lichen and bryophyte cover and richness.

## Bryophytes and lichen cover declined, litter increased

There was significantly lower cover and richness of bryophytes and lichens with warming, as well as increased litter cover (Figs. 2-3). Vascular plant cover and richness were not significantly affected. Species composition differed with and without warming, and warmed plots had taller vegetation and lower soil moisture (Fig. 4).

Fig. 1. The alpine peat-Dreis wetland in an open-heath landscape of Mt. Sanddalheiene (1230 m a.s.l.). Warming plots (black) were established in 2003 and 2006 (control plots). The 2003 increase in temperature by 2.1°C and soil moisture by 14% did not affect the vegetation in the control plots, while the 2006 increase by 1.3°C and 14% did increase the cover of vascular plants (Fig. 2). © G. Eiterjord.

## Species composition was affected by warming

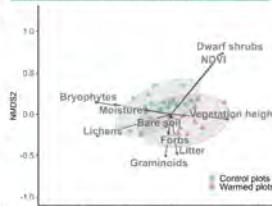

Fig. 2. Species richness in the three main groups of plants (vascular plants, lichens and bryophytes) in the control (n=16) and warmed plots (n=16) in 2003 warming. Dashed lines indicate significant differences between control and warmed plots. Error bars are one standard error of the mean. Letters above the bars indicate significant differences. \*\*\* p<0.001, \*\* p<0.01, \* p<0.05.

## Conclusion

Lichen and bryophyte cover and richness declined with warming, likely due to taller vegetation intercepting light and producing litter, with reduced soil moisture. As a result, the Dryas heath was impoverished and lost diversity. Our findings show the importance of including lichens and bryophytes when studying the effect of climate change on alpine plant communities.

# Plant sex expression, but not long-term experimental warming, affects the pollination success of *Silene acaulis*

Authors: Siri Lie Holgaard Prince<sup>1</sup>, Kari Klanderud<sup>1</sup>, Erik Trond Aschehoug<sup>2</sup>  
<sup>1</sup>Faculty of Environmental Sciences and Natural Resource Management, Norwegian University of Life Sciences, Ås, Norway  
<sup>2</sup>Centre for Biodiversity and Ecosystem Dynamics, University of Amsterdam, The Netherlands

## BACKGROUND

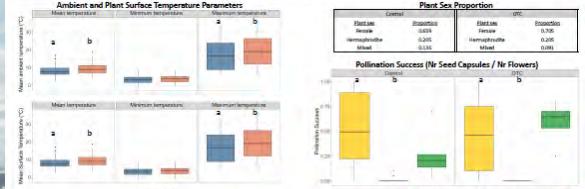

- Alpine ecosystems are defined by cold temperatures, strong winds and short growing seasons. These environments are sensitive to climate change, particularly rising temperatures.<sup>3</sup> *Silene acaulis* plays an important role in these habitats but is vulnerable to warming.<sup>4</sup>
- S. acaulis* exhibits sexual diversity, with mostly gynodioecious populations consisting of female and hermaphrodite individuals.<sup>5,6</sup> Mixed custers<sup>7</sup>, consisting of both female and hermaphrodite flowers on one individual, can also occur.<sup>8</sup>
- Studies have shown that *S. acaulis* may respond to increased temperatures with earlier flowering and changes in sex distribution.<sup>9,10</sup> This highlights the need for research into how alpine flora adapts to the shifts in climate.

## RESEARCH QUESTION

How does experimental warming and plant sex expression affect the pollination success of *Silene acaulis*?

## RESULTS

## FINDINGS AND DISCUSSION

- The OTC treatment significantly increased the ambient and plant surface temperatures compared to the control plants. The average daily temperature was increased by around 1°C and the average daily max around 3°C. When analysing the effect of OTC treatment on the pollination success, no effect was found.
- Plant sex had a pronounced effect on pollination success. Hermaphrodite plants had significantly lower success compared to female plants ( $p=0.001$ ).
- Male-acting hermaphrodites?<sup>11</sup> The male-acting hermaphrodites may be attributed to a resource allocation strategy. Producing pollen is more energy efficient than seed production. If the resources were limited, plants may reallocate resources towards male function, with a reduction in seed capsule production as a result.<sup>12</sup>
- Further research is needed to understand how plant sex expression and warming may affect the pollination success of *Silene acaulis*, with a particular focus on an adaptive response in resource allocation between male and female functions in hermaphrodites.

### Where, how and why?

Increased temperatures due to climate change will impact the biodiversity of alpine areas<sup>1</sup>. One of the most diverse plant communities in Scandinavia is the Heathland. We studied change in the alpine heathland at Finse, SW Norway, after 23 years of experimental warming (Fig. 1). We expected warming to increase dwarf shrub and graminoid cover at the expense of lichen and bryophyte cover and richness.

### Bryophytes and lichen cover declined, litter increased

There was significantly lower cover and richness of bryophytes and lichens with warming, as well as increased litter cover (Figs. 2–3). Vascular plant cover and richness were not significantly affected. Species composition differed with and without warming, and warmed plots had taller vegetation and lower soil moisture (Fig. 4).

### Fewer lichens and bryophytes reduced richness

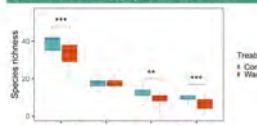

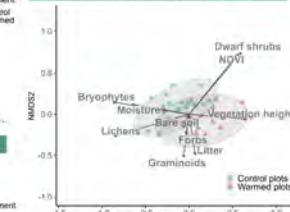

Fig. 1. The alpine Heathland Dyras in a plot with a chamber (OTC) and a control plot. The OTC increased in temperature by 2.1°C and soil moisture by 16% compared to the control plots. The OTC increases in temperature by 2.1°C and soil moisture by 16% compared to the control plots. The OTC increases in temperature by 2.1°C and soil moisture by 16% compared to the control plots.

<sup>1</sup>Studies have shown that *S. acaulis* may respond to increased temperatures with earlier flowering and changes in sex distribution.<sup>2,3</sup>This highlights the need for research into how alpine flora adapts to the shifts in climate.

### Species composition was affected by warming

### Conclusion

Lichen and bryophyte cover and richness declined with warming, likely due to taller vegetation intercepting light and producing litter, along with reduced soil moisture. As a result, the Dyras heath was impoverished and lost diversity. Our findings show the importance of including lichens and bryophytes when studying the effect of climate change on alpine plant communities.

• The OTC treatment significantly increased the ambient and plant surface temperatures compared to the control plants. The average daily maximum was increased by around 1°C and the average daily max around 3°C. When analysing the effect of OTC treatment on the pollination success, no effect was found.

## Plant sex expression, but not long-term experimental warming, affects the pollination success of *Silene acaulis*

### BACKGROUND

Alpine ecosystems are defined by cold temperatures, strong winds and short growing seasons. These environments are sensitive to climate change, particularly rising temperatures.<sup>1</sup> *Silene acaulis* plays an important role in these habitats but is vulnerable to warming.<sup>2</sup>

*S. acaulis* exhibits sexual diversity, with mostly gynodioecious populations consisting of female and hermaphrodite individuals.<sup>3,4</sup> Mixed custers,<sup>5</sup> consisting of both female and hermaphrodite flowers on one individual, can also occur.<sup>6</sup>

Studies have shown that *S. acaulis* may respond to increased temperatures with earlier flowering and changes in sex distribution.<sup>3,4</sup>This highlights the need for research into how alpine flora adapts to the shifts in climate.

### RESEARCH QUESTION

How does experimental warming and plant sex expression affect the pollination success of *Silene acaulis*?

**METHODS**  
Site: Sanddalenheiene, Finse, Norway

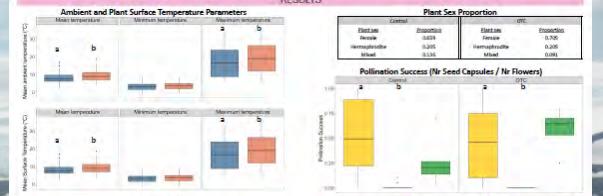

### Long-term experimental warming setup:

Open Top Chambers (OTCs) and control plots outside of the OTCs, established in 2000.

Temperature loggers:  
- TempSonic  
- DIY Science  
- Surface based  
- Surface and ambient temperature  
- Measures and logs every 15 minutes

### RESULTS

### FINDINGS AND DISCUSSION

• Ongoing evolution?  
- Hermaphrodites constitute a small portion of the studied *S. acaulis* population. As the only pollen producers, the mating system dynamics may be shaped by the limited availability of pollen. The genetic contribution of hermaphrodites would therefore be particularly important, suggesting an evolutionary trend driving resource allocation towards male function.

• Plant sex had a pronounced effect on pollination success. Hermaphrodite plants had significantly lower success compared to female plants ( $p=0.001$ ).  
• Male:acting hermaphrodites?  
- The hermaphrodites act like males: hermaphrodites may be attracted to a female flower to mate. Producing pollen is more energy efficient than seed production. If the resources were limited, plants may reallocate resources towards male function, with a reduction in seed capsule production as a result.<sup>8</sup>

• Future research is needed to understand how plant sex expression and warming may affect the pollination success of *Silene acaulis*, with a particular focus on an adaptive response in resource allocation between male and female functions in hermaphrodites.
